papers/0002-protomegatron-agent-loop/protomegatron_agent_loop.tex

Core definitions:

1. ProtomegaTron process state $P_t = \langle M, C, L, S, H, B, P_i, A, R, V \rangle$.
2. Hyperseed-scrutable agent loop: inspectable state, transitions, boundaries, memory updates, and provenance.
3. Medium-scale PeTTa memory K_{mid} : typed atom clusters for recent episodes, commitments, hypotheses, open questions, boundaries, and provenance.

Main conjecture:

Adding selective medium-scale PeTTa memory between pin/history and ChromaDB can improve continuity and self-scrutability if it remains typed, provenance-bearing, and periodically distilled.

Next steps: define atom schema; encode fresh-message and idle/no-input episodes; prototype medium-memory.metta API; compare against supervised OmegaClaw logs.
